

Attestable

Infrastructure risk has no financial counterparty.

Attestable is parametric coverage for blockchain infrastructure failure — settled by cryptographic proof of what happened on another chain, not by a claims process.

773.6 min

real Chainlink outage, settled on-chain

200 CTC

paid automatically, no human approval

51 / 51

tests passing, incl. 12 adversarial properties

Live

deployed on Creditcoin CC3 Testnet

Detection is a solved problem. Consequence isn't.

Every serious protocol already checks whether its price feed is stale. That check works. When the feed goes quiet, a lending protocol correctly **halts liquidations**.

And that is precisely when it starts losing money. Positions drift underwater, bad debt accrues, and the protocol absorbs it. **Detection converted one loss into another. It prevented nothing.**

Monitoring tells you that something went wrong.

Attestable lets someone **carry the financial consequence** of it.

Today this risk sits uninsured and unpriced on the balance sheet of every protocol that depends on an oracle. Risk committees cannot put a number on it, so they over-collateralise instead — which is expensive, and still doesn't pay out when it happens.

A policy with exactly two parties — and the provider isn't one of them.

The buyer

A protocol exposed to a feed it doesn't control. Pays a premium up front. Converts an unbounded tail risk into a budgetable monthly cost.

The underwriter

Posts collateral, keeps the premium if the feed behaves. Earns yield that is uncorrelated with market direction.

The subject

Chainlink. Signs nothing, stakes nothing, receives nothing, and need not know we exist — exactly like weather in a rainfall derivative.

Why that matters commercially: there is no business-development bottleneck. We never need a provider's permission, signature, or integration to launch a market on their infrastructure. That is the difference between a product and a partnership deal.

NOT A SIMULATION

We insured a real outage, and the chain paid it.

On **31 August 2026**, Chainlink's ETH/USD feed on Sepolia went silent for **12 hours 53 minutes**. We wrote a policy over that exact window with a 90-minute tolerance, proved the silence through Attestcoin, and let the contract settle itself.

OUTCOME	WORST SILENCE	TOLERANCE	PROOFS	SETTLEMENT
CLAIMED	773.6 min	90 min	2	0xdf52e5ad...
HEALTHY	61.6 min	90 min	7	0x801da47a...
HEALTHY	61.6 min	90 min	3	0x2c090c1d...

The number that proves we built against reality: the feed's **documented** heartbeat is 60 minutes. Its real worst gap on a perfectly healthy day is **61.6**. A policy written from the documentation would have paid claims against working infrastructure. Only measuring caught that.

Why this can only settle on Creditcoin.

The contract needs to answer two different questions, and Attestcoin is the only place both are answerable natively — with no bridge, no relayer quorum, and no trusted messenger.

Block Prover · 0x0FD2

“Did this happen?” Merkle inclusion against the source block's transaction trie, plus continuity down to a block the attester set signed.

ChainInfo · 0x0FD3

“Could evidence have been supplied by now?” Settlement is blocked until the attestation frontier passes the window's end.

That second question is the one that makes an absence-of-evidence outcome honest. Without it, a slow attester set — **our own infrastructure lagging** — would look identical to a real outage and could trigger a payout. We never claim to prove a negative. The finding is narrower and defensible: **insufficient valid evidence arrived before an attestation-safe deadline.**

Cryptography proves something happened; it cannot prove it was meaningful. Anyone can deploy a contract that emits a fabricated price and obtain a perfectly genuine proof of it. We check the emitter, the receipt status, and the event shape — and we ran that exact attack against the live precompile. It was rejected.

Who buys coverage.

They share one shape: their economics break when a feed they don't own goes quiet, and no amount of engineering on their side prevents it.

-

Lending protocols

— the sharpest case. A correct staleness check makes them halt liquidations, so positions drift underwater and bad debt accrues.

-

Perps and derivatives venues

— a stale mark price and funding rate means continuous bleeding to arbitrage for as long as the silence lasts.

-

Collateralised stablecoin issuers

— stale collateral valuation threatens the peg, which **is** the product.

-

Vaults, structured products, RWA platforms

— rebalancing and mark-to-market stop dead when the feed stops.

The buyer's real motive is not the payout. It is turning an unbounded tail risk into **a line item**. For the first time a risk committee can attach a number to “we depend on an oracle”.

Who underwrites it.

-

DeFi funds and yield desks

— almost all DeFi yield is market beta. Oracle-liveness premium is

uncorrelated with market direction

, which is scarce. And because every update is public and timestamped, the risk is unusually modelable.

-

Market makers and volatility desks

— already price tail events; this is cleaner data than most of what they trade.

-

The infrastructure operator itself

— the strongest angle we found.

A newer oracle network competing with Chainlink can underwrite coverage on its own feed. **“We pay you if we go stale”** is a financial commitment, not a marketing claim.

That is also the cleanest answer to **“why not just let the provider fix it?”** — underwriting is **how a provider proves they fixed it**. It hands operators a procurement weapon they currently do not have.

What each policy brings to Creditcoin.

Not a one-off transaction. A cover is an **ongoing on-chain relationship** for its entire life.

Two funded participants

A buyer and an underwriter, both needing CTC, who otherwise had no reason to transact on Creditcoin at all.

Recurring proof traffic

Every qualifying feed update is a separate verification transaction — continuous activity for the whole window, not a single settlement.

Escrow as TVL

Collateral and premium sit locked on-chain for the duration of every active cover.

And the reason they come is structural, not promotional: **Creditcoin is the only place the contract can settle**, because it is the only chain that natively verifies what happened on Ethereum. The demand isn't for a token — it's for a capability that exists nowhere else.

Roadmap.

HORIZON	WHAT SHIPS	WHY IT MATTERS
Now	Chainlink feed liveness on Sepolia, settled on Creditcoin	Working, deployed, with real settlements on a real outage
Next	One design partner	A mid-sized lending protocol already burned by oracle latency. This is the real milestone — it is commercial, not technical.
Then	Multi-chain evidence in a single policy	Mainnet is already attested and the aggregator resolves; we cut it rather than ship it half-working
Then	Policy registry and pooled underwriting	Capital efficiency — one pool backing many covers instead of 1:1 collateral
Later	Beyond price feeds: bridges, sequencers, DA layers	Any infrastructure whose failure is observable on-chain is insurable the same way

Emmanuel Aje Ayoola

Solo founder and sole engineer. Nigeria.

Contracts, worker, frontend, tests, deployment and documentation — all of it. What I would ask you to judge is not headcount, but the decisions:

-

I
attacked
my own
contract
and
published
what I
found.

Two exploits — instant collateral drain via a missing wall-clock check, and retrospective purchase of coverage whose outcome was already observable. Both fixed; both now regression-tested.

-

I measured instead of trusting documentation.

The 61.6-minute finding exists because I refused to write a policy from a spec sheet.

-

I found a
bug on
submission
day that

would have
made the
demo a lie.

Our evidence scanner used a fixed lookback shorter than the policy window, manufacturing a 314-minute outage that never happened. I fixed the scanner and left that cover

rather than settle money on a number I knew was wrong.

- **The wrong turns are still in the commit history.**

A history with no mistakes in it looks manufactured.

If we win the \$10,000.

CertiK audit credits and Skynet Boost come with the placement, so none of this duplicates security audit spend. Every line below buys the one thing this project actually lacks: **a first real counterparty.**

ALLOCATION	AMOUNT	WHAT IT UNBLOCKS
Underwriting seed capital	\$4,000	Capitalise the first live covers so a design partner can buy protection that genuinely pays. Without capital on the supply side there is no market to join.
Founder runway	\$3,000	Three months to ship multi-chain evidence and the policy registry.
Archive infrastructure & mainnet	\$1,500	A year of archive RPC access plus mainnet deployment and monitoring. Archive access is the literal reason multi-chain was cut.
Regulatory opinion	\$1,500	A preliminary view on where a parametric on-chain instrument can be offered, and to whom. Unanswered, this blocks every serious buyer.

What we do not claim.

No signed customers

The risk is measured and the loss mechanism is concrete, but nobody is hedging oracle-staleness today. Every party in this deck is prospective.

We don't judge correctness

We cover silence, never inaccuracy. Judging whether a price was **right** would require an oracle — the dependency we exist to make survivable.

Trust isn't eliminated

It is relocated. Trust remains in Attestcoin's attestor set and in the feed's honesty about itself. This is a working prototype, not a regulated insurance product.

We state this plainly because the alternative is worse. A judge who catches you overclaiming discounts everything else you said — and the limits here are narrow enough that naming them costs us nothing.

The three questions we expect.

"WHY IS THE DATA ON ETHEREUM AT ALL?"

Because it already is. Chainlink's node operators publish it there for their own reasons — we didn't create it, can't influence it, can't fake it. That's exactly what makes it credible evidence.

"IS THERE REALLY A MARKET FOR THIS?"

Honestly — unproven. The risk is measured and the loss mechanism is concrete, but nobody is hedging oracle-staleness today and we have no signed customers. Our next milestone isn't technical, it's one design partner: a lending protocol that's already been burned by oracle latency and remembers it.

"WHAT'S LEFT TO BUILD?"

Multi-chain evidence in one policy. Mainnet is already attested and we confirmed the aggregator resolves — we couldn't get the archive access to finish it, so we cut it rather than ship something half-working.

Nothing here needs to be taken on trust.
